Abstract

Global warming and air pollution have become one of the important issues to the entire world community. Exhaust emissions from ships has been contributing to the health problems and environmental damage. This study focuses on the Strait of Malacca area because it is one of the world's most congested straits used for international shipping where located on the border among three countries of Indonesia, Malaysia and Singapore. The study seeks to estimate of the exhaust emission and to know the concentration of emission to several areas around. This is accomplished by evaluating the density of shipping lanes in the Straits of Malacca by using the data which obtained by Automatic Identification System (AIS). MEET methodology is used to estimate emissions from ships and Gaussian Puff Model used to estimates the concentration in several areas around the Strait. The results show 813 total number of ships through the Strait of Malacca on September 2, 2011 at 07.00 am-08.00 am produces exhaust emission for NO_x, CO, CO₂, VOC, PM and SO_x are about 13715.5 g/second, 25461.52 g/second, 11092.9 g/second, 5858.2 g/second, 415.3 g/second and 6921.7 g/second, respectively. The ships under the Singapore flag contribute approximately 22.72% of total emissions in the Strait of Malacca followed by Panama and Liberia flag approximately 21.32%, 12.89%, respectively. Ships under Malaysia and Indonesia rank of sixth and seventh respectively of the emission rates. The most high-risk areas which affected by the emissions are Sentosa Island (Singapore), Port of Pasir Gudang (Malaysia) and Jurong Island (Singapore) with approximately contaminated about 47.33%, 21.68% and 17.69%, respectively of total emission and other areas around the Strait represent below 1%.

Keywords: Ship emissions, AIS, MEET, Gaussian Puff Model, , Straits of Malacca and Singapore

1. Introduction

Global warming and air pollution have become one of the important issues to the entire world community. About 80% of the international trade and movement of goods carried by ship through the sea [23] cause exhaust emission from marine traffic which contribute to the global warming and air pollution problems. Wang [25] estimated 64,000 cardiopulmonary, lung cancer mortalities and 92% premature death as globally caused by Particulate Matter (PM) from ship traffic.

The Straits of Malacca and Singapore are one of the most important shipping channels in the world connecting the Indian Ocean with the South China Sea and the Pacific Ocean. The Straits remains as one of the world's most congested straits used for international shipping. Approximately over 60,000 vessels pass through the Straits annually [14], the Strait play role in producing of shipping emission and contributed to air pollution.

Previous attempts, [18] by using ATMOS (Atmospheric Transport Modeling System) showed that shipping emission of sulfur oxide (SO₂) on the Strait of Malacca almost the same in Sumatra,

Indonesia (32,000 t SO₂ of Strait of Malacca and 52,000 t SO₂ per year of Sumatra) and approximately one-quarter of the total emissions in each of Singapore and Malaysia [2].

This study focuses on the Strait of Malacca and Singapore area because it is one of the world's most congested straits used for international shipping where located on the border among three countries of Indonesia, Malaysia and Singapore. The objective of this study is to estimate the air pollution such as SO_x, NO_x, CO, CO₂ and Particulate Matter (PM) resulting from the marine traffic in the Strait of Malacca and Singapore areas using Automatic Identification System (AIS) data. The same method previously have conducted by [7][8], [15] and [17]. AIS data are used as an initial data (raw data), it can identify Maritime Mobile Service Identity (MMSI) of ship, ship speed, initial position and type of ship. The such data is used to evaluate the traffic density of the Strait of Malacca and Singapore area. The initial data will combine with ship database to obtain gross tonnage (GT) of the ship for emission estimation consideration. Once emission is calculated, an emissions dispersion model of the Gaussian Puff Model is used to estimate the concentration of emission in several areas around the Strait which caused by distribution of the emissions. In addition, a programming using Microsoft Visual Studio 2010 is built to ease the calculation of emission and the distribution by the reason of using several variations of time release on calculation of the Gaussian Puff Model.

2. Literature Review

Over the years, there were many study efforts in emission's estimations fields such as [9], [25][11], [13], [5] and [12]. [25]estimated emissions of 172,000 ship voyages to and from North American ports in 2002 by using Ship Traffic, Energy, and Environment Model (STEEM) and also evaluated the energy use. [11]estimated NO_x and PM₁₀ emission from marine traffic in the Italian harbor of Ravenna by using Transport Emissions and Energy Consumption Methodology (MEET Methodology). Ship's data taken by considering the number of ships in the harbor. The study also evaluated the contribution of emission to air quality by using ADMS-URBAN model, Atmospheric Dispersion Modelling System (ADMS) is a dispersion model of pollutants released into the atmosphere from industrial, domestic and traffic sources in urban areas. [13]estimated the atmospheric emissions from international shipping (carbon dioxide, sulfur dioxide and nitrogen oxides) in the Belgian area of the North Sea for a one year period. [5]estimated emission of exhaust gases and particles from

seagoing ships as globally. They use different approach to estimate the emission such as Top-down approaches to calculate the fuel consumption, Bottom-up approaches to estimate shipping and route specific emissions based on ship movements, ship attributes, and ship emission factors, Ship Traffic, Energy and Environment Model (STEEM) and geographic information system (GIS) technology is used to solve routes automatically at a global scale, following actual shipping routes. The ship's data taken by considering the number of oceangoing fleet of ships for the year 2001 from Lloyd's Maritime Information System (LMIS) (2002).[12]evaluated the impact of ship emission in coastal areas of the North Sea under conditions of the year 2000. Estimation of ship emission on this study using approach on the basis of ship movement data together with average engine loads and emission factors. To simulate the atmospheric transport and transformation of air pollutants, they used A three-dimensional Eulerian chemistry transport model. The vessel database was purchased from Lloyds Marine Intelligent Unit (LMIU). It consists of a vessel characteristic database and a vessel movement database and it includes all commercial vessels equal to or greater than 100 gross tonnages (GT).

The Strait of Malacca and Singapore is one of the world's most congested straits used for international shipping. The Straits are one of the heavy marine traffic. Consequently, that it causes air pollution levels are high. [18]estimated sulfur dioxide from international shipping in Asian waters. They estimated sulfur dioxide in sea line by using The RAINS-ASIA project methodology and estimated the emission in major ports by considering the number of ships from 12 different ports in Asia waters, assumed that the typical ship is a 70,000 dwt cargo vessel averaging 11 knots and 18 t of oil consumption per day and traveling in the port vicinity for 6 h and calculated using a method for port emissions found in the literature is a reference in CONCAWE (1993). The approach for deposition of this sulfur was calculated using the ATMOS model of atmospheric transport and deposition. The result of this study for The Straits of Malacca areas, showed that land areas most heavily affected are those bordering the Strait of Malacca, where portions of Sumatra, peninsular Malaysia, and Singapore have contributions from shipping in excess of 10% of total sulfur deposition. Emissions within the Strait of Malacca, measured from the northwestern tip of Sumatra (4S°N latitude, 93.5°E longitude) to Singapore, are estimated to be 39,400 t SO₂ per year. As compared to [2] and [3] showed that shipping emission of sulfur oxide (SO₂) on the Strait of Malacca almost the same in Sumatra, Indonesia (32,000 t SO₂ of Strait of Malacca and

52,000 t SO₂ per year of Sumatra) and approximately one-quarter of the total emissions in each of Singapore and Malaysia.

Initially, Automatic Identification System (AIS) has been used to comply security regulations since September 11, 2001, functioning as traffic management, collision avoidance, and other safety applications. However, today, Automatic Identification System (AIS) be able used to estimate ships emissions. Jalkanen [7] purposed a modeling system for maritime traffic exhaust emissions of NO_x, SO_x, and CO₂ in the Baltic Sea area based on data obtained from AIS receivers. The approach for estimating emission of by using ship Traffic, Energy, and Environment Model (STEEM). In the year of 2011, Jalkanen et al (2012) extends the research for ship emission of particulate matter (PM) and carbon monoxide (CO) and presented Ship Traffic Emissions Assessment Model (STEAM2) as a method for estimation of ship emissions. Perez [15] uses AIS by combining with Geographic Information System (GIS) to spatially analyze the emissions of marine vessels. However, AIS doesn't provide completeness of ship information such as main engine power, auxiliary engine power, and gross tonnage. Therefore, additional of ship information is needed from ship database as Lloyd's Register. The study propose for estimated the emission of nitrogen oxides (NO_x), carbon monoxide (CO), non-methane volatile organic compounds (NMVOC), sulfur dioxide (SO₂), ammonia (NH₃), particulate matter less than or equal to 10 µm (PM₁₀), particulate matter less than or equal to 2.5 µm (PM_{2.5}), and several significant hazardous air pollutants for Texas State waters for ship that recorded in years of 2007 by using Swedish Methodology for Environmental Data's (SMED) Methodology for calculating emission from ships. Pitana[17] estimated the ship emission level of nitrogen oxides (NO_x), sulfur oxides (SO_x), particulate matter (PM), carbon monoxide (CO) and carbon dioxide (CO₂) in the Strait of Madura, Indonesia by using Automatic Identification System (AIS) receiver to obtain ship data. The study used a combination of GIS and AIS data to evaluate ship traffic patterns and combining AIS data with ship databases for retrieving gross tonnage (GT) information of ship which is then used to estimate the ship's emission. Emission estimates are based on the standard European (MEET) methodology, which is adopted from [19][20].

3. Methodology

The methodology of the study indicates stages of the working process of the study. The study framework started from an investigation of AIS

raw data to be several databases such as information relating to ship speed and locations (longitude & latitude), MMSI number of ships, ship departure and arrival speeds, types and names of ship, etc. could be obtained. In addition, for calculation using the Gaussian Puff Model needs AIS data relating to MMSI number, receive time and positions of shipment for each proposed time release. Ship data of Gross Tonnage (GT) that could not be obtained from AIS receivers were extracted from free ship databases, such as marinetraffic.com, maritime-connector.com, equasis.org, vesseltracker.com and Equasis.org. In order to evaluate ship traffic patterns, AIS data is input into the ArcGIS software suite. Ship traffic patterns are useful when evaluating ship operational modes, such as maneuvering, hotelling and cruising which is necessary for determining their emission factors. Figure 1 shown overall framework of the study.

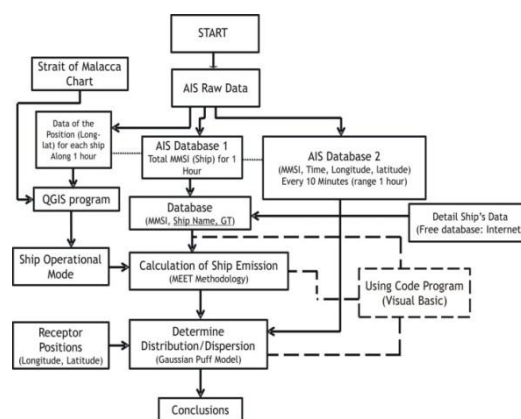

Figure 1. Framework of the study

3.1 Overview of AIS Installation

Primary data of ships which obtained from an AIS receiver in the study are MMSI of the ship, IMO number, receive time, the position of the ship (longitude and latitude), speed of ground (SOG) and COG. These all the data obtained from an AIS receiver installed in Marine Technology Laboratory (Marine Technology Center (MTC), Faculty of Mechanical Engineering, Universiti Teknologi Malaysia (UTM) as shown in the Figure 2. The AIS data collected was simultaneously stored and updated in a hard disk on the Personal Computer (PC). Once recorded, such data could be utilized by other users using local network or the internet.

Figure 2. AIS Installation in the UTM, Marine Technology Center

Automatic identification systems (AIS) are designed to be capable of providing information about the ship to other ships and to coastal authorities automatically for ship 300 gross tonnage and above engaged on international voyages, cargo ships of 500 gross tonnage and upwards not engaged on international voyages and all passenger ships irrespective of size [6]. IMO Resolution MSC.74 (69) requires each ship included in the regulation shall provide information including the ship's identity, type, position, course, speed, navigational status and other safety-related information. Information update rates of AIS also includes on the [6]. AIS information of every ship is needed to update at specified time frame. The different information types are valid for a different time period and thus need a different update.

- i. Static information shall update at every 6 min and on request
- ii. Dynamic information shall update dependent on speed and course alteration according to the Table 1
- iii. Voyage related information shall update at every 6 min, when data have been amended and on request
- iv. Safety-related message shall update as required

Table 1. Information updates rates for AIS

Type of ship	Reporting interval
Ship at anchor	3 min
Ship 0-14 knots	12 Sec
Ship 0-14 knots and	4 Sec
Ship 14-23 knots	6 Sec
Ship 14-23 knots and	2 Sec
Ship > 23 knots	3 Sec
Ship > 23 knots and	2 Sec

3.2 Analysis of AIS Data

To identify the ship traffic in the Strait of Malacca, a program of the MySQL Database Management is used to obtain required data for the purposes of emissions calculation and the distribution assessment. Trozzi[19] [20] mentioned that air pollution emissions are influenced by the traffic density, ship types and ship operational modes. From the emissions point of view, operational modes considered are the maneuvering phase, hotelling phase and cruising phase.

Figure 3 and 4 shows the traffic density data recorded on September 2011 and September 2, 2011 in term of average number of ships per day and per hour, respectively.

Figure 3. Number of ships on September 2011

From Figure 3 shows the total number of ships on September 2011. For instance, there were about 1530 ships and 1474 ships recorded during days on September 1 and September 6, respectively. The figure shows the lowest marine traffic density was recorded on September 29 by the total number about 1364 ships while the densest occurred on September 2 by the total number about 1587 ships during the day.

In this research, we focus on September 2, 2011 as the densest period of marine traffic, as shown in the Figure 4. On that day, it can be seen that the busiest periods occurred around the hours of 0400, 0800 and 0900. We selected 0800 which showed the highest level of marine traffic. There were recorded about 1173 ships passing through the Strait of Malacca during 0800 (0700-0800) on September 2. For the purpose of calculation and the distribution of emissions, only selects 813 numbers of ships from the total 1173 ships that occurred on that day. The remaining number of ships can not be used in the calculation because there were invalid data of the ships that recorded by AIS receiver. The invalid data were often occurring on MMSI number and IMO number, the invalid data

cannot be used to find additional of ships data on free database. Table 2 shows the total number of ships by type during 0800 on September 2, it can be seen that there were about 360 unknown or invalid ships.

Figure 4. Number of ships September 2, 2011

In addition to the marine traffic density data, it is very important to analyze the ship types as shown in the Figure 5(a) since the ship types influence emission factors [19] [20]. Figure 5 (a) and Table 2 shows that the majority of ships recorded at 0800 on September 2 were Solid Bulk, tug boat and container, followed by other ships, general cargo, solid bulk, passenger, ro-ro cargo, high speed ferries and fishing vessel.

Table 2. Total number of ships (by type)

Type	Number of Ship
Solid Bulk	49
Liquid Bulk	372
General Cargo	51
Container	124
Ro-Ro Cargo	3
Passenger	12
High speed ferries	1
Tugs	138
Fishing	1
Other	62
Unknown/invalid ships	360
Total Number of Ship	1173
Total correspondent ship	813

Figure 5(b) shows the majority of ships by mode operational recorded on that day were hotelling, maneuvering and cruising. Figure 5(c) shows the majority of flag registered ship recorder at 0800 on September 2, it can be seen the highest number of ships were by flag of Singapore, others flag, Panama and Liberia, followed by the Marshall Islands, Malaysia, Indonesia, Hong Kong, China, Bahamas, Malta, Cyprus, Vietnam and China Peoples's Republic.

Figure 5. Total number of ships on September 2, 2011 (a) by type (b) by mode operation (c) by flag registered

3.3 Emission Assessment Assumption

The calculation of emission is calculated based on the standard European (MEET) methodology which is primarily based on the work [19][20] and UNECE/EMEP (2002) and also used by [17]. There are 12 class of ships which considered on the assessment that have gross tonnage in excess of 100 GT, using appropriate emission factors, and specific ship parameters such as engine type, time spent in port, fuel consumption and gross tonnage.

Methodologies for estimating air pollutant emissions from ships used to estimate of consumption and emissions based on present day statistics of ship traffic [19][20] and [22]. Fuel consumption of any type of ship are obtained from a linear regression analysis of fuel consumption to gross tonnage as shown in the Table 3. Calculation of emissions rate defined as:

$$E_i = \sum_{jklm} E_{ijklm} \dots\dots\dots (1)$$

$$E_{ijklm} = S_{jkm}(GT) \cdot t_{jklm} \cdot F_{ijlm} \dots\dots\dots (2)$$

Where

- i : pollutant
- j : fuel type
- k : ship class for use in consumption

l : engine type class for use in emission factors
 s : reference reduction scenario (low, medium, high)
 E_i : total emissions of pollutant i
 E_{ijklm} : total emissions of pollutant i from use of fuel j on ship class k with engines type l in mode operation m
 $S_{jkm}(GT)$: daily consumption of fuel j in ship class k as a function of gross tonnage
 T_{jklm} : days in navigation of ships of class k with engines type l using fuel j in mode operational m
 F_{ijlm} : average emission factors of pollutant i from fuel j in engines type l in mode m .

For auxiliary engine (generator) [19][20] use the following equation which got from [4]. The equation has adopted by Ishida (2003) to estimate air pollution and greenhouse gases from ships. The equation is defined as:

$$f = P \times L \dots\dots\dots(3)$$

Where

f : Auxiliary engine fuel consumption

P : Auxiliary engine rated output

L : Load factor

Table 3. Ship class & fuel consumption

Ship types(code)	Consumption at full power (t/day) as function of gross tonnage
------------------	--

Solid Bulk (SB)	$C_{jk} = 20.1860 + 0.00049 \times GT$
Liquid Bulk / Tanker (LB)	$C_{jk} = 14.6850 + 0.00079 \times GT$
General Cargo (GC)	$C_{jk} = 9.8197 + 0.00143 \times GT$
Container (CO)	$C_{jk} = 8.0552 + 0.00235 \times GT$
Ro-Ro Cargo (PC)	$C_{jk} = 12.8340 + 0.00156 \times GT$
Passenger (PA)	$C_{jk} = 16.9040 + 0.00198 \times GT$
High Speed Ferry (HS)	$C_{jk} = 39.4830 + 0.00972 \times GT$
Inland Cargo (IC)	$C_{jk} = 9.8197 + 0.00143 \times GT$
Sail Ship (SS)	$C_{jk} = 0.4268 + 0.00100 \times GT$
Tugs (TU)	$C_{jk} = 5.6511 + 0.01048 \times GT$
Fishing (FI)	$C_{jk} = 1.9387 + 0.00448 \times GT$
Other Ships (OT)	$C_{jk} = 9.7126 + 0.00091 \times GT$

Trozzi[20] update them research towards the methodology for estimating emissions from navigation in the frame of maintenance of the EMEP/EEA air pollutant emission inventory. In the Table 4, [20] reported the results of the non-linear regression procedure applied to installed main engine power by considering several ship classes as a function of gross tonnage. In this study, the table is used to estimate the power of the main engine. Power of auxiliary engine is calculated by using the vessel ratio of Auxiliary Engines / Main Engines as shown in Table 5, once the power of the main engine is calculated from Table 4. Load factor used for estimates of auxiliary engine fuel, based on Table 6 given by [20].

Table 4. Installed main engine power as a function of gross tonnage (GT)

Ship categories	2010 World fleet	1997 World fleet	Mediterranean Sea fleet (2006)
Liquid bulk ships	$14.755 * GT^{0.6082}$	$29.821 * GT^{0.5552}$	$14.602 * GT^{0.6278}$
Dry bulk carriers	$35.912 * GT^{0.5276}$	$89.571 * GT^{0.4446}$	$47.115 * GT^{0.504}$
Container	$2.9165 * GT^{0.8719}$	$1.3284 * GT^{0.9303}$	$1.0839 * GT^{0.9617}$
General Cargo	$5.56482 * GT^{0.7425}$	$10.539 * GT^{0.6760}$	$1.2763 * GT^{0.9154}$
Ro Ro Cargo	$164.578 * GT^{0.4350}$	$35.93 * GT^{0.5885}$	$45.7 * GT^{0.5237}$
Passenger	$9.55078 * GT^{0.7570}$	$1.39129 * GT^{0.9222}$	$42.966 * GT^{0.6035}$
Fishing	$9.75891 * GT^{0.7527}$	$10.259 * GT^{0.6919}$	$24.222 * GT^{0.5916}$
Other	$59.049 * GT^{0.5485}$	$44.324 * GT^{0.5300}$	$183.18 * GT^{0.4028}$
Tugs	$54.2171 * GT^{0.6420}$	$27.303 * GT^{0.7014}$	

Table 5. Estimated average vessel ratio of Auxiliary Engines/Main Engines by ship type

Ship category	2010 World fleet	Mediterranean Sea fleet (2006)
Liquid bulk ships	0.3	0.35
Dry bulk carriers	0.3	0.39

Container	0.25	0.27
General cargo	0.23	0.35
Ro Ro Cargo	0.24	0.39
Passenger	0.16	0.27
Fishing	0.39	0.47
Others	0.35	0.18
Tugs	0.1	

Table 6. Estimated % load of MCR (Maximum Continuous Rating) of Main /Auxiliary Engine for different ship activity

Phase	% load of MCR Main Engine	% time all Main Engine operating	% load of MCR Auxiliary Engine
Cruise	80	100	30
Manoeuvring	20	100	50
Hotelling (except tankers)	20	5	40
Hotelling (tankers)	20	100	60

3.3 Definitions of hotelling, maneuvering and cruising

The operational mode of the ship is used to measure emission resulting from ship activities. Mode operational ships of hotelling, maneuvering and cruising are used when estimating fuel consumption and emissions [19][20] and [22]. When the ships spend approaching, docking and departing the harbor called as maneuvering. Hotelling refers to operations taking place while ships are berthed alongside piers, while ships traveling at a constant speed are said to be cruising [17]. Mode operational of the ships is shown in Figure

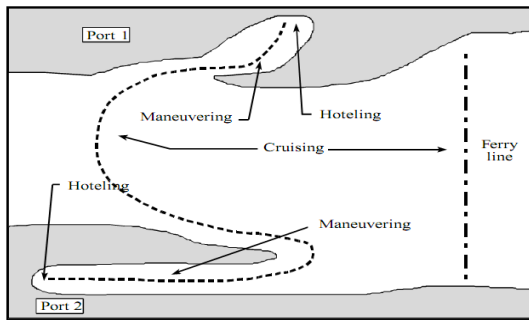

Figure 6. Ship movement characteristics

3.4 Assumption on Assessment of Emissions Distribution

The Gaussian puff model is used to estimate the concentration of emission and its more likely to be an instantaneous release rather than a continuous emission. The way to use the Gaussian puff model gas adopted by [1] and [10]. The Gaussian puff model is defined as:

$$Cr = \frac{Q \cdot \Delta t}{(2\pi)^{1.5} \cdot \sigma_x \sigma_y \sigma_z} \cdot \exp\left(\frac{-(x_r - Ut)^2}{2 \sigma_x^2}\right) \cdot \exp\left(\frac{-(z_r - He)^2}{2 \sigma_z^2}\right) \cdot \exp\left(\frac{-y_r^2}{2 \sigma_y^2}\right) \left[\exp\left(\frac{-(z_r - He)^2}{2 \sigma_z^2}\right) + \exp\left(\frac{-(z_r + He)^2}{2 \sigma_z^2}\right) \right] \quad (4)$$

Where:

Cr : the concentration at receptor
(xr, yr, zr): the Cartesian coordinates downwind of the puff

Q: the emission rate

Ut: the wind speed

Δt: the length of time of the release itself,

σx, σy, σz: the standard deviations of the concentration distribution in the x-, y-, and z-directions, respectively

The Gaussian model is an analytical solution to the 3D advection-dispersion equation with the following assumptions [Altwick 2000]:

- Wind speed is constant,
- The system is at steady state,
- Diffusion in the x-direction is ignored and the other diffusion coefficients are anisotropic,
- The plume can be reflected from the ground when an image source is added and mass is conserved
- Contaminant is conservative,
- Gas is assumed to be ideal and inert.

Pingjian[16] use Gaussian model and do the transfer coordinate to get the real value of x as shown in Figure 7. The wind direction is x in Gaussian puff equations (equation 4). The transfer coordinates equation defined as:

$$x = x_0 * (\cos \theta / \cos \beta) \quad (5)$$

$$y = y_0 * (\sin \theta / \sin \beta) \quad (6)$$

$$\alpha = \beta + \theta \quad (7)$$

Figure 7. Transfer coordinates (Pingjian et al, 2006)

In the equation of the Gaussian puff model (equation 4), standard deviation σx, σy, σz depend on the downwind distance and the atmospheric

stability class. The uncertainty of the vertical dispersion coefficient, σ_z , was varied with downwind distance and stability class in a manner consistent with the fundamental form of the Pasquill-Gifford functions [21]. These coefficients in meters can be obtained from the equations utilized by the Industrial Source Complex (ISC) Dispersion Model developed by [24]:

$$\sigma_y = 465.11628 (x) \tan(\text{TH}) \dots\dots\dots(8)$$

Where:

$$\text{TH} = 0.01745 [c - (d) \ln(x)] \dots\dots\dots(9)$$

$$\sigma_z = a.x^b \dots\dots\dots(10)$$

The formula and corresponding parameter values for determining the lateral diffusion coefficient for a Gaussian plume as shown in Equation 8, 9 and 10 by using the fundamental form of the Pasquill-Gifford functions [21][24].

Once known amount of emission released by the respective ships passing through the Strait of Malacca, the next step is calculated distribution of the emission. The total emission of ships will be seen in several areas around the Strait of Malacca. The areas are figured as a point which has a position of longitude and latitude and called as "receptor". There are 51 points of receptor around the Strait which to be placed as a reference point to know the distribution of the emission as shown in Figure 8.

Figure 8. 51 points of receptor surrounding the Strait of Malacca areas

In this study, time release of the emission is varied by 6 range of time. At time of 10 minutes, 20 minutes, 30 minutes, 40 minutes, 50 minutes and 59 minutes. Time reference is 60 minutes because all the calculation only at 1 hour (08.00am on September 2, 2011). Thus, time releases is obtained at $\Delta t.1 = 50 \text{ min}$, $\Delta t.2 = 40 \text{ min}$, $\Delta t.3 = 30 \text{ min}$, $\Delta t.4 = 20 \text{ min}$, $\Delta t.5 = 10 \text{ min}$ and $\Delta t.6 = 1 \text{ min}$

3.4 Calculation by Programming

Calculation of emission and the concentration are performed by using programming. The high number of calculation and output of the calculation becomes an issue when it calculated by manually. The programming which used for this step is Microsoft Visual Studio 2010.

4. Result and Analysis

4.1 Programming Overview

Calculation of emission and the distribution will generate a huge number of calculations and result. This happens because of the usage Gaussian Puff Model which considers several of time release. There are 6 time release are considered in this study, thus generates results in huge of number. Because of the issue, thus made a program using Microsoft Visual Studio 2010 (VB) program as shown in Figure 9.

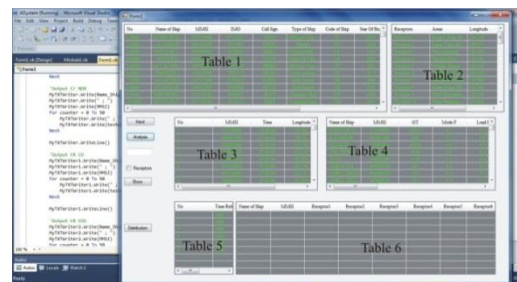

Figure 9. Programming of emission calculation and the distribution

Encoding functions to calculate emission rates of ships is based on equation 1, 2 and 3. The result shows fuel consumption of fuel main engine, auxiliary engine and emissions rate each ship showed in table 4 by programming. Encoding functions to calculate the concentration of emission for every point of receptors based on Equation 4-10. The result will show the concentration rate of emission to each receptor by programming. The total output of result is formatted in the form of text file and saved on the local computer drive. The output is resulted for every time release showed in table 6 by programming and one text file format for each emission. The programming needs an input data in Microsoft excel format and containing several data of AIS and the additional data, receptor data, ship position (longitude and latitude) for every time release and time release data.

4.2 Total emissions

The estimation results for NO_x, CO, CO₂, VOC, PM and SO_x emissions from ships is shown in Table 7. The results show that NO_x, CO, CO₂, VOC, PM and SO_x rates were 13715.51 g/second, 25461.525 g/second, 11092.99 g/second, 5858.216 g/second, 415.304 g/second and 6921.746 g/second, respectively. In addition, the highest emissions rate of NO_x, CO, CO₂, VOC, PM and SO_x for a single hours were emitted by liquid bulk (tanker), which contributed 4353.872 g/second, 11212.623 g/second, 4549.125 g/second, 2590.807 g/second, 170.592 g/second and 2843.203 g/second, respectively at 0800 September 2, 2011. It is also possible to estimate exhaust emission by considering the vessel's flag of registry, as shown in Tables 8. These tables show that the most significant contributions to emissions were from ships registered under the flag of Singapore. They also show that NO_x, CO, CO₂, VOC, PM and SO_x emissions were 2641.152 g/second, 6226.438

g/second, 2513.719 g/second, 1441.283 g/second, 94.157 g/second and 1569.275 g/second, respectively.

Table 7. Estimates of NO_x, CO, CO₂, VOC, PM and SO_x during the densest marine traffic conditions in the Strait of Malacca area at 08.00 September 2, 2011.

Type of ships	NO _x	CO	CO ₂	VOC	PM	Sox
(g/ton of fuel) per-second

4.3 Concentration of Emission on Surrounding Areas of Malacca Strait

There are 51 points of receptor around the Strait which to be placed as a reference point to know the distribution of the emission at 0800 September 2, 2011 as shown in Figure 8. The receptor point divided into 4 major area includes Indonesia areas (14 receptors), Malaysia areas (15 receptors) Singapore areas (10 receptors) and open sea areas on around the Malacca Strait (12 receptors). Figure 10-15 shows concentration of emission for NO_x, CO, CO₂, VOC, PM and SO_x emission on the surrounding Strait of Malacca areas. The distribution of ships emissions were calculated on all ships movement includes hotelling, cruising and maneuvering condition. These conditions are considered by the current position of ship for each time release which converted from Lat-Long to UTM (Universal Transverse Mercator) coordinate.

The result shows that NO_x, CO, CO₂, VOC, PM and SO_x were concentrated on areas of Singapore and Malaysia. The most high-risk areas which affected by the emissions are Sentosa Island (Singapore), Port of PasirGudang (Malaysia) and Jurong Island (Singapore). Sentosa Island (Singapore) contaminated by NO_x, CO, CO₂, VOC, PM and SO_x emission were 8.51×10^{-6} µg/m³, 7.25×10^{-7} µg/m³, 3.13×10^{-6} µg/m³, 2.35×10^{-7} µg/m³, 1.174×10^{-7} µg/m³ and 1.957×10^{-6} µg/m³, respectively at 0800 September 2, 2011 at a time release of 10 minutes on Gaussian Puff Model calculations. Concentration of NO_x, CO, CO₂, VOC, PM and SO_x emission in the Port of PasirGudang (Malaysia) were 4.60×10^{-7} , 5.97×10^{-8} , 2.58×10^{-7} , 1.94×10^{-8} , 9.69×10^{-9} and 1.61×10^{-7} µg/m³, respectively and in the Jurong Island (Singapore) were 1.19×10^{-7} , 5.13×10^{-7} , 1.66×10^{-7} , 1.20×10^{-7} , 6.21×10^{-9} and 1.04×10^{-7} µg/m³, respectively for NO_x, CO, CO₂, VOC, PM and SO_x

emission at 0800 September 2, 2011 at a time release of 10 minutes.

6. Conclusion and Recommendation

In this paper, we demonstrated that it is possible to use AIS data to estimate NOx, SOx, PM, CO and CO₂ emissions and distribution of the emission from shipping activities. In additions, the distribution can be seen through amount of concentration of emission in several areas around the ship traffic as an emission source. This study also demonstrated that possibility of calculating the distribution of emission by all mode operational of ships (Manoeuvring, cruising and hoteling), not only one of them.

The Exhaust emission rates which produced through this study may used for evaluating the impact of marine traffic on air quality, the greenhouse effect and could be used when establishing government policy in relation to ratification of international maritime conventions, such as MARPOL 73/78 Annex VI (Pitana et al, 2010).

This study showed the total amount of emission NOx, CO, CO₂, VOC, PM and SOx emission were 13715.51 g/second, 25461.525 g/second, 11092.99 g/second, 5858.216 g/second, 415.304 g/second and 6921.746 g/second, respectively. It also showed that the highest contribution of emission per hour from liquid bulk (tanker), which contributed 4353.872 g/second, 11212.623 g/second, 4549.125 g/second, 2590.807 g/second, 170.592 g/second and 2843.203 g/second at 0800 September 2, 2011, respectively. In addition, this study also determined possibility to evaluate the emissions by considering the vessel's flag of registry. Furthermore, our study showed that the total distribution of emission surrounding areas of the Malacca Strait.

There are 51 areas that we consider in this paper, but only 3 areas were shown in this result of the paper as the highest-affected areas of emission from marine traffic in the Strait of Malacca on 0800 September 2, 2011. The most high-risk areas which affected by the

emissions in that hour are Sentosa Island (Singapore), Port of PasirGudang (Malaysia) and Jurong Island (Singapore) with approximately contaminated about 47.33%, 21.68% and 17.69%, respectively of total emission and other areas around the Strait represent below 1%. We also consider wind direction on exhaust gas emission to calculate the distribution of emission according to the wind direction that occurs in the Strait of Malacca on 0800 September 2, 2011 which the data was obtained from the Malaysian Meteorological Department (2011).

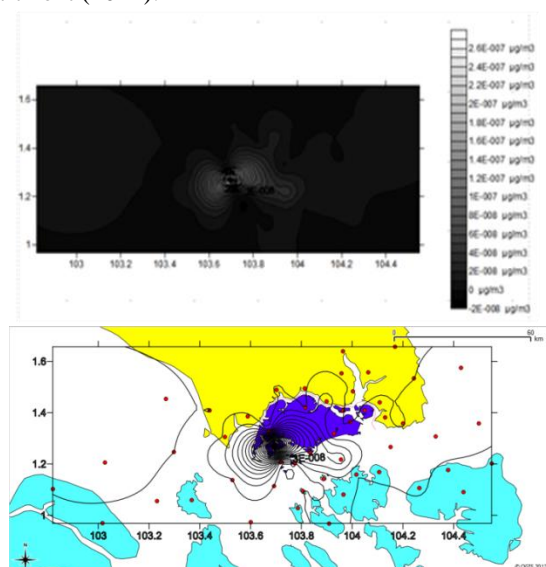

Figure 16. Distribution of NOx emission by Surfer.8 at t=20 minutes

Calculation of the emission distribution using the Gaussian Puff Model enables to find out the total concentration of emission at specified time intervals and predetermined distance. Result of total emission distribution by the usage of the model shown a tendency to decline over time. For example, Figure 16 and 17 are the total of distribution of NOx emission at release time t=20 minutes and t=50, respectively. These Figure shows a tendency of the concentration from $4.35216\text{E}-08 \mu\text{g}/\text{m}^3$ at t=20 to $6.94188\text{E}-10 \mu\text{g}/\text{m}^3$ at t=59. It is caused by several factors when emission was distributed over time influenced by wind direction and time release emitted.

This study only determines exhaust emission and distribution. The impact of such emissions on human beings was not evaluated. In additions, additional database of ships as complementary AIS Data to get complete data on the ship, in the future research will be necessary.
